

Proposition:  $\mathbb{T} \subseteq \mathbb{T}_\lambda = \omega > \lambda$  trees

$\mathbb{T}$  is noetherian  $\iff \exists$  depth function  $d: \mathbb{T} \rightarrow |\mathbb{T}|^+$

Proof: " $\Leftarrow$ " Suppose  $\mathbb{T}$  is not noetherian  $\implies$

$\exists \eta: \omega \rightarrow \lambda$  such that  $[\eta] \subseteq \mathbb{T}$

Let  $d: \mathbb{T} \rightarrow |\mathbb{T}|^+$  be given  $\implies$

$d(\eta \upharpoonright n)$  ( $n < \omega$ ) is a strictly decreasing sequence

$\downarrow$  ordinals

" $\Rightarrow$ " Let  $\mathbb{T}$  be noetherian.

Let  $\max \mathbb{T} =$  all maximal branches of  $\mathbb{T}$

$\mathbb{T}_0 = \max \mathbb{T}$ ,  $\mathbb{T}^0 = \mathbb{T} \setminus \mathbb{T}_0$  is a tree

Put  $d: \mathbb{T}_0 \rightarrow |\mathbb{T}|^+$  ( $v \mapsto 0$ )

$\mathbb{T}_1 = \max \mathbb{T}^0$ ,  $\mathbb{T}^1 = \mathbb{T}^0 \setminus \mathbb{T}_1$ ,  $d: \mathbb{T}_1 \rightarrow |\mathbb{T}|^+$  ( $v \mapsto 1$ )

(and so on). At limits  $\alpha$ , put  $\mathbb{T}^\alpha = \bigcap_{\beta < \alpha} \mathbb{T}^\beta$

$\implies \exists \alpha < |\mathbb{T}|^+ \wedge \mathbb{T}^\alpha = \mathbb{T}^{\alpha+1}$

If  $\mathbb{T}^\alpha \neq \emptyset \implies$  construct  $\eta: \omega \rightarrow \lambda$ ,  $[\eta] \subseteq \mathbb{T}^\alpha \iff \mathbb{T}$  noetherian

$\implies \mathbb{T}^\alpha = \emptyset \implies d$  a total map  $\mathbb{T} \rightarrow |\mathbb{T}|^+$   
a depth function  $\square$

Corollary: "Noetherian subtrees of  $\mathbb{T}_\lambda$  are absolute", i.e. ...

THEOREM: If  $\lambda < \kappa(\omega)$  and  $\mathbb{T}_\lambda = \omega > \lambda$ , then there exists a family  $\mathcal{T}_\lambda = (\mathbb{T}_\alpha, c_\alpha) (\alpha \in 2^\lambda)$  of absolutely rigid trees  $\mathbb{T}_\alpha \subseteq \mathbb{T}_\lambda$  with colouring  $c_\alpha: \mathbb{T}_\alpha \rightarrow \{0, 1\}$ .

Proof:  $\lambda < \kappa(\omega) \xrightarrow{\text{Silver}} \lambda \xrightarrow{vw} \omega_2^{<\lambda}$ , i.e

$\exists c: \omega > \lambda \rightarrow 2$  but  $\nexists \eta \in \omega \lambda^\neq$  such that  $c(\eta \uparrow n) = c(\eta^- \uparrow n) \forall n < \omega$   $\square$

Recall  $\eta \in \dots \lambda^\neq =$  all neighbours  $\eta(i) \neq \eta(i+1)$  are distinct

$\eta^- = (\cancel{\eta(0)}, \eta(1), \eta(2), \dots)$   
 $\mathbb{T}[v] = \{ \eta \in \mathbb{T} \mid \eta \subseteq v \text{ or } v \subseteq \eta \}$   
 $\alpha < \lambda \Rightarrow \langle \alpha \rangle \in \mathbb{T}$

Define  $\mathbb{T}(0) = \{ \perp \}$ ,  $\mathbb{T}(n) \subseteq {}^n \lambda^\neq$ , then

$\mathbb{T}(n+1) = \{ v \in {}^{n+1} \lambda^\neq \mid v \uparrow n, v^- \in \mathbb{T}(n), c(v \uparrow n) = c(v^-) \}$ ,  
 $\Rightarrow \mathbb{T} = \bigcup_{n < \omega} \mathbb{T}(n)$  is a tree with depth

Proposition  $\Rightarrow \mathbb{T}$  is noetherian

Define  $\mathbb{T}_\alpha = \mathbb{T}[\langle \alpha \rangle] (\alpha < \lambda)$   
 $\mathcal{T}_\lambda = (\mathbb{T}_\alpha, c \upharpoonright \mathbb{T}_\alpha) (\alpha < \lambda)$   
 is an absolutely rigid family of trees.

Show: rigid

Let  $M \subset N$  be transitive models of ZFC

and  $\mathcal{T}_\alpha$  ( $\alpha < \lambda$ ) a family in  $M$

Suppose  $\exists \beta, \gamma < \lambda$  and  $f: \mathcal{T}_\beta \rightarrow \mathcal{T}_\gamma$  homo in  $N$ .

Construct  $\eta: \omega \rightarrow \lambda$   $\wedge$   $[\eta] \subseteq \mathcal{T}$  ( $\nexists$  noetherian)

Put  $\eta(0) = \beta$

induction: Suppose  $\eta \upharpoonright n \in \mathcal{T}'_\beta$

define  $\eta \upharpoonright n+1 \in \mathcal{T}'_\beta$

with  $f(\eta \upharpoonright n) = f(\eta \upharpoonright n)$

$\boxtimes$   $\wedge$   $f$  preserves colour  $c$ , and  $\mathcal{T}'(n+1)$

$\Rightarrow \eta \upharpoonright n+1 \in \mathcal{T}'_\beta \Rightarrow [\eta] \subseteq \mathcal{T}'_\beta \subseteq \mathcal{T}$   $\blacksquare$

Enlarge  $\mathcal{T}_\alpha$  ( $\alpha < \lambda$ ):

Choose  $\mathcal{F} \subseteq \mathcal{P}(\lambda)$  such that

$|\mathcal{F}| = 2^\lambda$   $\wedge$   $\mathcal{F}$  an antichain

(i.e.  $\forall X \neq X' \in \mathcal{F} \Rightarrow X \not\subseteq X' \wedge X' \not\subseteq X$ )

Define  $\mathcal{T}_X = \bigcup_{\alpha \in X} \mathcal{T}[\langle \alpha \rangle]$ ,  $c_X = c \upharpoonright \mathcal{T}_X$

$\Rightarrow (\mathcal{T}_X, c_X)$  ( $X \in \mathcal{F}$ ) is

absolutely rigid families of trees  $\subseteq \mathcal{T}_\lambda$ .

Suppose that the branches of length  $< n + 1$  are constructed. Given any branch

$$\eta : n \longrightarrow \{[t_i] \dot{\cup} \{\omega, \omega + 1, \omega + 2, \omega + 3\}\}$$

of length  $n$ , then  $\nu$  is a successor of  $\eta$  of length  $\text{lg}(\nu) = n + 1$  if  $\nu(n)$  satisfies one of the following conditions.

- If  $\eta(n - 1) \notin \omega^*$  and  $(n - 1) \in S_\omega$ , then  $\nu(n) \in \eta(n - 1)$ .
- If  $\eta(n - 1) \notin \omega^*$  and  $(n - 1) \notin S_\omega$ , then  $\nu(n) = \eta(n - 1)$
- If  $\eta(n - 1) \in \omega^*$  and  $n - 1 \notin S_{\eta(n-1)}$ , then  $\nu(n) = \eta(n - 1)$ .
- If  $\eta(n - 1) \in \omega^*$  and  $n - 1 \in S_{\eta(n-1)}$ , then  $\nu(n) \in \{\omega, \omega + 1\}$ .
- If  $\eta(n - 1) \in \{\omega, \omega + 1\}$ , then  $\nu(n) \in \{\omega + 2, \omega + 3\}$ .

This completes the construction of the rigid family  $\mathcal{T}$  of  $\lambda$ .
